January 10, 2014

M. Collowald, A. Cuyt, E. Hubert, W.-s. Lee, O. Salazar Celis nD-shape-from-moments problem

n-dimensional shape-from-moments problem

Reconstruct a polytope ${\mathcal P}$ from a finite set of its moments.

Retrieve ${\mathcal V}$ the set of vertices of ${\mathcal P}$ from moments.

Previously

- 2D-case solved by computing complex vertices and using numerical methods (Milanfar *et al.* 95, Golub *et al.* 99)
- convex polytopes solved for exact computation using Brion's identities (Gravin, Pasechnik, Lasserre, Robins 12)

Our method

Combine numerical methods of the 2D-case with theoretical results of the higher dimensional case; solve the underlying problems with an algorithm numerically valid.

Plan

Directional moments

- Real, complex and directional moments
- Brion's identities

2 Recovering the vertices from directional moments

- Prony's method and Pencil method
- Matching the coordinates of the vertices together
- Estimating the number of vertices

3 Simulations

- First example : regular hexagon
- Second example : polygon with 12 vertices
- Third example : non-convex polygon
- Diamond

Real, complex and directional moments Brion's identities

- Real, complex and directional moments
- Brion's identities

2 Recovering the vertices from directional moments

3 Simulations

Real, complex and directional moments Brion's identities

Consider a polytope \mathcal{P} in \mathbb{R}^n .

Real moments of order k

$$m_{k_1,k_2,\ldots,k_n} = \int_{\mathcal{P}} x_1^{k_1} x_2^{k_2} \ldots x_n^{k_n} dx_1 dx_2 \ldots dx_n,$$

with $k_1 + k_2 + \ldots + k_n = k$.

Complex moment of order k

$$m_k(1,i) = \int_{\mathcal{P}} z^k dx_1 dx_2$$
, where $z = x_1 + i x_2$.

Directional moment of order k

$$m_k(\delta) = \int_{\mathcal{P}} \langle x, \delta \rangle^k dx = \int_{\mathcal{P}} (x_1 \delta_1 + \ldots + x_n \delta_n)^k dx_1 dx_2 \ldots dx_n,$$

where δ is the unit vector on the direction.

M. Collowald, A. Cuyt, E. Hubert, W.-s. Lee, O. Salazar Celis

Real, complex and directional moments Brion's identities

Brion's identities

Consider a convex polytope \mathcal{P} in \mathbb{R}^n with r vertices. Assume that the orthogonal projections on the direction δ of the vertices in \mathcal{V} are distinct. Then

$$rac{(k+n)!}{k!(-1)^n}\,m_k(\delta) = \sum_{egin{smallmatrix} v\in\mathcal{V}\ k!(-1)^n \end{pmatrix}} a_k(\delta) = \sum_{egin{smallmatrix} v\in\mathcal{V}\ k\in\mathcal{V} \end{pmatrix}} a_{egin{smallmatrix} a_{eta}(\delta)\ \langle v,\,\delta
angle^k, & 0\leq k\leq n-1, \end{pmatrix}$$

where the coefficients $a_v(\delta)$ depend on δ and the adjacent vertices of v in a triangulation of \mathcal{P} . Moreover

$$a_v(\delta) \neq 0 \quad \forall \ v \in \mathcal{V}.$$

Real, complex and directional moments Brion's identities

Case of a simple convex polytope \mathcal{P}

In this case, the coefficients $a_v(\delta)$ are given by

$$a_{\mathbf{v}}(\delta) = rac{V_{\mathbf{v}}}{\prod\limits_{u \in K_{\mathbf{v}}} \langle u - \mathbf{v}, \delta
angle}$$

where V_v is the volume of the parallelepiped K_v defined by the edges adjacent to v.

Real, complex and directional moments Brion's identities

Davis' formula

For any polygon \mathcal{V} in the complex plane and for any analytic function f,

$$\iint_{\mathcal{V}} f''(z) \, dx_1 dx_2 = \sum_{v \in \mathcal{V}} a_v \, f(v),$$

where v are the complex vertices.

In this case, the coefficients a_v - or $a_v(\delta)$ with $\delta=(1,\mathrm{i})$ - are given by

$$\mathsf{a}_{\mathsf{v}}(\delta) = rac{\mathsf{V}_{\mathsf{v}}}{\prod\limits_{u\in \mathsf{K}_{\mathsf{v}}} \langle u-\mathsf{v},\delta
angle},$$

where V_v is the volume of the parallelogram K_v defined by the edges adjacent to v.

From the moments to an appropriate sequence

Consider the sequence $(\mu_k)_{k\in\mathbb{N}}$ defined by

$$\begin{cases} \mu_k = 0 & \text{for } 0 \le k \le n-1 \\ \\ \mu_k = \frac{k!(-1)^n}{(k-n)!} m_{k-n}(\delta) & \text{for } k \ge n. \end{cases}$$

Prony's method and Pencil method Matching the coordinates of the vertices together Estimating the number of vertices

From the moments to an appropriate sequence

Consider the sequence $(\mu_k)_{k\in\mathbb{N}}$ defined by

$$\begin{cases} \mu_k = 0 & \text{for } 0 \le k \le n-1 \\ \\ \mu_k = \frac{k!(-1)^n}{(k-n)!} m_{k-n}(\delta) & \text{for } k \ge n. \end{cases}$$

Thus we have a sequence $(\mu_k)_{k\in\mathbb{N}}$ such that

$$\mu_k = \sum_{i=1}^r a_i \, w_i^k, \; \forall k \in \mathbb{N},$$

with a_1, \ldots, a_r non-zero real numbers and $\mathcal{V}(\delta) = (w_1, \ldots, w_r)$ the sought numbers.

Reconstruction of a *n*-dimensional convex polytope \mathcal{P} with *r* vertices if an upper bound *R* is known.

Algorithm

- estimating the number of vertices r.
- recovering the projections $\mathcal{V}(\delta) = \{ \langle v, \delta \rangle \mid v \in \mathcal{V} \}$ of the *r* vertices of *P* from its directional moments *m_k(δ)*.
- **③** recovering the set of vertices \mathcal{V} from n+1 sets $\mathcal{V}(\delta)$.

Key assumption

The projections of the vertices on the chosen directions δ are pairwise distinct.

Prony's method and Pencil method Matching the coordinates of the vertices together Estimating the number of vertices

Estimating the number of vertices

Factorization of the Hankel matrix H_0 of size $k \times k$, $k \ge 1$

 $H_0 = W^t A W,$

where W is the Vandermonde matrix of size $r \times k$ defined by the set of projected vertices $V(\delta)$ and A is the diagonal matrix of size $r \times r$ whose elements are the non-zero coefficients $a_v(\delta)$.

Numerical rank by Singular Values Decomposition

If an upper bound R for r is known,

then analysing the singular values of the Hankel matrix H_0 of size $R \times R$ gives us an estimation of r.

Directional moments Recovering the vertices from directional moments Simulations	First example : regular hexagon Second example : polygon with 12 vertices Third example : non-convex polygon Diamond
--	---

Conclusion

At the moment, advantages

- less directions are needed than in previous polygon reconstruction (Milanfar *et al.* 95)
- generalization in any dimension with a robust matching process

Next directions

- finding a better optimization process for the reference direction
- solving similar problems, using multivariate methods (generalized Hankel matrices), like

multivariate exponential interpolation,

cubature formula.
