Continuous Measures

Questions and Problems

The Dimension Problem

Consider any real X of positive effective Hausdorff dimension (positive asymptotic entropy), i.e.

$$\liminf_{n\to\infty}\frac{\mathsf{K}(X\!\upharpoonright_n)}{n}>0$$

Question

Does X compute a Martin-Löf random (λ -random) real?

Continuous Measures

Questions and Problems

The Von-Neumann Trick

Given a coin with bias p, use it to produce an unbiased coin toss:

Toss the coin twice. If the outcomes are identical, discard and toss anew, otherwise interpret HT as H and TH as T.

This is an example for extracting randomness from a random source of lower entropy. In the following we make this precise.

Continuous Measures

Questions and Problems

Notation for Cantor Space

- Elements of 2^{ω} are called reals.
- Finite initial segments of reals are strings.
- The (partial) prefix order on $2^{<\omega} \cup 2^{\omega}$ is denoted by \Box .
- $\bullet\,$ The basic clopen cylinder induced by a string σ is

$$\mathfrak{U}(\sigma) := \{ X \in 2^{\omega} : \ \sigma \sqsubset X \}.$$

• If $C \subseteq 2^{<\omega}$, we write $\mathcal{U}(C)$ to denote the open set

$$\mathfrak{U}(\mathsf{C}) = \bigcup_{\sigma \in \mathsf{C}} \mathfrak{U}(\sigma).$$

Continuous Measures

Questions and Problems

Measures on Cantor Space

Using Caratheodory's extension theorem, measures on 2^{ω} have a convenient representation.

It allows to identify premeasures with measures.

Definition

A measure on 2^{ω} is a function $\mu: 2^{<\omega} \to [0, \infty)$ such that for all $\sigma \in 2^{<\omega}$

 $\mu(\sigma) = \mu(\sigma 0) + \mu(\sigma 1).$

If $\mu(2^{\omega}) = \mu(\varepsilon) = 1$, μ is a probability measure.

In the following, all measures are assumed to be probability measures.

 λ denotes the uniform measure $\lambda(\sigma)=2^{-|\sigma|},$ which is isomorphic to Lebesgue measure on [0,1].

Continuous Measures

Questions and Problems

Randomness

Definition

Let μ be a computable measure.

• A μ -Martin-Löf test is a uniformly enumerable sequence $(C_n)_{n \in \mathbb{N}}, C_n \subseteq 2^{<\omega}$ such that for every $n \in \mathbb{N}$

$$\sum_{\sigma \in C_n} \mu(\sigma) \leqslant 2^{-n}$$

2 A sequence $R \in 2^{\omega}$ is Martin-Löf random with respect to μ (μ -random), if for all μ -Martin-Löf tests $(C_n)_{n \in \mathbb{N}}$

$$R\not\in \bigcap_{n\in\mathbb{N}}\mathfrak{U}(C_n).$$

Continuous Measures

Questions and Problems

Bernoulli Randomness

If μ_p is the (p,1-p)-Bernoulli measure (0 $1), then for every <math display="inline">\mu_p\text{-random real}$ X it holds that

$$\liminf_{n\to\infty} \frac{\mathsf{K}(X{\upharpoonright}_n)}{n} = \mathsf{H}(\mu_p) = -[p\log p + (1-p)\log(1-p)] > 0$$
 (Levin, Lutz)

Von Neumann's trick ensures that, for reals random relative to a (computable) Bernoulli measure, it is always possible to extract a λ -random sequence.

Continuous Measures

Questions and Problems

Image Measures

Let μ be a measure and $f:2^{\varpi}\rightarrow 2^{\varpi}$ be a continuous (Borel) function.

Define a new measure μ_f by setting

 $\mu_f(\sigma)=\mu(f^{-1}\mathfrak{U}(\sigma))$

Observation: If μ {X} = 0 for all X $\in 2^{\omega}$, then, for

$$f(X) = \mu\{Y: \ Y < X\},$$

it holds that $\mu_f = \lambda$.

Continuous Measures

Questions and Problems

The Isomorphism Theorem

Definition

Let μ be a measure on 2^{ω} .

- X is called an atom for μ if μ {X} > 0.
- µ is continuous if it has no atoms.

Theorem

For every continuous measure μ there is a Borel isomorphism f of 2^{ω} such that $\mu_f=\lambda.$

Continuous Measures

Questions and Problems

Randomness Conservation

Idea: If the transformation f is computable, then it should preserve randomness, i.e. it should map a μ -random real to a μ_f -random one.

Note: If μ is a computable measure, then a real A is μ -random iff A is an atom of μ .

Theorem (Levin, Kautz)

If a real is nonrecursive and random with respect to a computable measure, then it is Turing equivalent to a λ -random real.

Measures and Transformations

Arbitrary Measures

Continuous Measures

Questions and Problems

Dimension and Randomness

So, is every real of positive dimension random with respect to a computable measure?

Theorem

For every rational 0 < r < 1 there is a real X such that

$$\liminf_{n\to\infty}\frac{\mathsf{K}(X\!\upharpoonright_n)}{n}=\mathsf{r},$$

and X is not random with respect to any computable measure.

Proof.

Join a 1-generic and a λ -random real with appropriate density.

Continuous Measures

Questions and Problems

Randomness for Arbitrary Measures

But von Neumann's trick works for non-computable measures, too.

We extend Martin-Löf's notion of randomness to arbitrary measures.

Denote by $\mathfrak{M}(2^{\omega})$ the space of all probability measures on 2^{ω} .

Fact

 $\mathfrak{M}(2^{\omega})$ is compact metrizable and Polish.

There is an effective representation of $\mathfrak{M}(2^{\varpi})$ as a recursively bounded tree.

σ

Continuous Measures

Questions and Problems

Randomness for Arbitrary Measures

Definition

Let $\mu \in \mathfrak{M}(2^{\omega})$. A Martin-Löf test for μ is a sequence $(V_n)_{n \in \mathbb{N}}$ of subsets of $2^{<\omega}$ such that (V_n) is uniformly r.e. in μ and for each n,

$$\sum_{\in V_n} \mu(\sigma) \leqslant 2^{-n}.$$

Note that every real is trivially random with respect to some μ if it is an atom of μ .

We are interested in the case when a real is non-trivially random.

Measures and Transformations

Arbitrary Measures

Continuous Measures

Questions and Problems

The Duality Question

Is there a relation between the complexity of a real and the complexity of a measure that makes it (non-trivially) random?

Continuous Measures

Questions and Problems

Randomness is Non-Recursiveness

Recursive reals are only trivially random.

But they are the only reals for which this holds.

Theorem (Reimann and Slaman)

If X is a non-recursive real, then there is a measure μ such that $\mu\{X\} \neq 0$ and X is $\mu\text{-random}.$

Continuous Measures

Questions and Problems

Randomness is Non-Recursiveness

Theorem (Reimann and Slaman)

If X is a non-recursive real, then there is a measure μ such that $\mu\{X\} \neq 0$ and X is $\mu\text{-random}.$

The proof is based on the following idea:

- Image measures "push" measure forward. Randomness is conserved. The distribution function pushes forward to Lebesgue measure.
- We have a real and have to find a measure that makes it random.
- Instead of pushing measure forward, use a λ-random real and "pull" Lebesgue measure back.

Continuous Measures

Questions and Problems

Randomness is Non-Recursiveness

The basic outline of the proof is as follows. We want to make a real $X >_T \emptyset$ random relative to a measure μ such that $\mu\{X\} = 0$.

- Succera's Theorem yields that every real ≥_T Ø' is Turing-equivalent to some λ-random real.
- 2 The theorem relativizes.
- Use the Posner-Robinson Theorem to make X look like a jump (relative to some C).
- Bence X is T-equivalent (relative to C) to some λ^{C} -random real R.
- Use the T-equivalence to devise a Π⁰₁ set of measures which are "pull backs" of λ.
- O Conclude that X is μ^{C} -random and hence μ -random.

Measures and Transformations

Arbitrary Measures

Continuous Measures

Questions and Problems

Relativizing Kučera's Theorem

Theorem

If $X \ge_{T(C)} C'$, then there exists a λ^C -random real R such that $X \equiv_{T(C)} R$.

Essential for the proof is the (relativized) Coding Lemma.

Lemma

Let (U_n) be a universal ML^C -test for some measure μ . Let \mathcal{P}_n be the $\Pi^0_1(C \oplus \mu)$ -class of μ^C -random reals given by the nth level of the test. Then there exists a function $g: 2^{<\omega} \times \mathbb{N} \to \mathbb{Q}^{>0}$ recursive in $C \oplus \mu$ such that for any $\sigma \in 2^{<\omega}$ and any $n \in \mathbb{N}$ it holds that

$$\mathfrak{P}_n\cap\mathfrak{U}(\sigma)\neq\emptyset\quad\Rightarrow\quad\mu\mathfrak{U}(\sigma)\geqslant g(\sigma,n).$$

Measures and Transformations

Arbitrary Measures

Continuous Measures

Questions and Problems

The Posner-Robinson Theorem

Theorem (Posner and Robinson)

If X is not recursive, then there exists a C such that

 $X\oplus C \geqslant_{\mathsf{T}} C'$

Continuous Measures

Questions and Problems

Pulling Back the Measure

Combining the relativized version of Kučera's Theorem with the Posner-Robinson Theorem, we conclude that there exists reals C, R such that

R is
$$\lambda^{C}$$
-random and $X \equiv_{T(C)} R$

So assume that Φ and Ψ are Turing functionals recursive in C such that

$$\Psi(X)=R \quad \text{and} \quad \Phi(R)=X.$$

We will use Φ and Ψ to control the pull back of λ .

Pulling Back the Measure

We want to define $\mu(\sigma)$, $\sigma \in 2^{<\omega}$.

Let
$$\operatorname{Pre}(\sigma) := \{ \tau \in 2^{\omega} : \Phi(\tau) \sqsupseteq \sigma \& \Psi(\sigma) \sqsubseteq \tau \}$$
.

If we want to define a measure μ with respect to which X is random, we have to satisfy two requirements:

- The measure μ will dominate an image measure induced by Φ. This will ensure that any Martin-Löf random sequence is mapped by Φ to a μ-random sequence.
- Provide the advantage of the measure must not be atomic on X.

To meet these requirements, we restrict the values of μ in the following way (if Φ and Ψ are defined):

 $\lambda(\mathsf{Pre}(\sigma)) \leqslant \mu(\sigma) \leqslant \lambda(\Psi(\sigma))$

Questions and Problems

Pulling Back the Measure

(1)
$$\operatorname{Pre}(\sigma) := \{ \tau \in 2^{\omega} : \Phi(\tau) \supseteq \sigma \& \Psi(\sigma) \sqsubseteq \tau \}.$$

(2) $\lambda(\operatorname{Pre}(\sigma)) \leqslant \mu(\sigma) \leqslant \lambda(\Psi(\sigma))$

Every configuration given by (2) corresponds to a subtree of ${\mathfrak M}(2^{\omega}).$

Every string being enumerated into $\mathsf{Pre}(\sigma)$ cuts off a branch in $\mathcal{M}(2^\omega).$

It follows that

 $M := \{\mu: \ \mu \text{ satisfies (2)}\}$

```
is a \Pi_1^0 subset of \mathcal{M}(2^{\omega}).
```

Questions and Problems

A Basis Theorem for Relative Randomness

We want to show that for some $\mu \in M$, X is μ -random.

Note that if (V_n) is a ML^C-test, $\Psi(V_n)$ is a ML^{C \oplus \mu}-test.

So, what we need to show is that R is $\lambda^{C \oplus \mu}$ -random for some $\mu \in M$.

Theorem (independently by Downey, Hirschfeldt, Miller, and Nies)

If $\mathcal{B} \subseteq 2^{\omega}$ is nonempty and Π_1^0 in C, then, for every R which is λ^C -random there is $A \in \mathcal{B}$ such that R is $\lambda^{C \oplus A}$ -random.

The proof is essentially a compactness argument.

Continuous Measures

Questions and Problems

Randomness and Continuous Measures

It seems desirable to further classify the reals by their randomness properties in the sense of the Duality Problem.

Can we improve the result that every non-recursive real is random with respect to some measure in the sense that it is actually random with respect to a measure without atoms, i.e. a continuous measure?

The answer turns out to be "no". For some reals atoms are essential.

Continuous Measures

Questions and Problems

Not Continuously Random Reals

Call a real continuously random if it is random with respect to some continuous measure. We denote the class of reals that are not continuously random by NCR.

Theorem (Kjos-Hanssen and Montalban)

If X is a member of a countable Π_1^0 class, then $X \in NCR$.

Proof.

- With respect to a continuous measure, every countable set has always measure 0.
- A Π₁⁰ class of measure 0 cannot contain a random real.

Continuous Measures

Questions and Problems

Facts About NCR

- Members of countable Π_1^0 classes are hyperarithmetic.
 - Kreisel, 1959
- There are members of countable Π⁰₁ classes at all levels of the hyperarithmetical hierarchy.
 - Cenzer, Clote, Smith, Soare, and Wainer, 1986
- What about elements of NCR outside the hyperarithmetic reals?
- Is NCR countable?
- NCR is a Π_1^1 class without a perfect subset.
 - It follows from work by Mansfield, Solovay that NCR \subseteq L.

A Sufficient Condition for Continuous Randomness

What does ensure the existence of a continuous measure that makes a real random?

An analysis of the proof of the "Every Nonrecursive Real is Random"-Theorem yields the following condition:

If $X \leq_T R$, where R is a λ -random real, and $R \leq_{wtt} X$, then X is random with respect to some continuous measure.

Continuous Measures

Questions and Problems

Woodin's Theorem and NCR

Woodin showed if X is not hyperarithmetic, then there exists some C such that

$X\oplus C \geqslant_{tt(C)} C'.$

Woodin's theorem enables us, when outside the hyperarithmetical sets, to code a real into a tree of random reals (relative to some *C*) by means of a wtt-reduction.

Theorem

If X is not hyperarithmetic, then there exists a continuous measure μ such that X is μ -random.

Questions and Problems

- Is every real in NCR a member of a countable Π⁰₁ class, i.e. is NCR the union of all countable Π⁰₁ classes?
- What is the class of reals which are 2-random with respect to some (continuous) measure? Which reals are never (continuously) 2-random?
 - Working conjecture (Slaman): There are only countably many not continuously 2-random reals.
- Which reals compute a measure with respect to which they are random?
 - Note that such reals can, by relativizing Levin-Kautz, compute a λ-random real.
 - Working conjecture: There exists an upper cone of such reals.

Continuous Measures

Questions and Problems

Questions and Problems

- What is the complexity needed for a measure that makes a complex real random?
 - Working conjecture: If

$$\liminf_{n} \frac{\mathsf{K}(X\!\upharpoonright_n)}{n} = s > 0,$$

then there exists a Δ_2^0 -computable measure μ such that

$$\mu(\sigma) \leqslant c 2^{-|\sigma|s}$$
,

with respect to which X is random.
