ABSTRACT. Let A be a finite cyclic group and let f be a non-zero complex valued function defined on A. Donoho and Stark gave an elementary proof that the product of the cardinality of the support of f and the cardinality of the support of the Fourier transform of f is greater than or equal to the order of A. They also described the set of functions for which the equality holds. We provide an elementary proof of a generalization these results to the case when A is an arbitrary finite abelian group.

0. Introduction. The main purpose of this note is to provide an elementary proof for an uncertainty principle on a finite abelian group. By an uncertainty principle we mean an inequality involving (the concentration of) a function and its Fourier transform, along with its minimizers, that is, all functions achieving equality. Such minimizers are of interest in signal representation, see e.g. [P-D-Ö] and its references.

The uncertainty principle we consider states that the product of the cardinalities of the supports of a (non-zero complex valued) function and its Fourier transform, defined on a finite abelian group, is at least the order of the group. Moreover, the minimizers are indicator functions of subgroups up to translations, modulations and scalar multiples. When the group is cyclic an elementary proof of the inequality and the determination of its minimizers was given by Donoho and Stark, [D-S], hence the title of this note.

However, (for any finite abelian group) the inequality immediately follows from the earlier work of Matolcsi and Szücs [M-S], and the determination of minimizers

---

from that of K. T. Smith [S]*. Another proof is a consequence of an entropy based uncertainty principle, [Ö-P], and will be explained in section 1. These proofs are short but not elementary and are consequences of other uncertainty principles (involving L^p norms or entropy) in the more general context of a locally compact abelian group. Our elementary proof, in section 2, uses no more than basic concepts from finite dimensional linear algebra over complex numbers and the structure of finite abelian groups.

1. The Uncertainty Principle.

Let A be a finite abelian group and let $\hat{A}$ be the dual group (consisting of all characters, i.e. group homomorphisms $\alpha : A \to \mathbb{C}^\times$). For a function $f : A \to \mathbb{C}$ define the Fourier transform

$$\hat{f}(\alpha) = \sum_{a \in A} f(a)\, \alpha(-a), \qquad (\alpha \in \hat{A}),$$

a modulation

$$M_\beta f(a) = \beta(a) f(a) \qquad (\beta \in \hat{A},\ a \in A),$$

and a translation

$$T_c f(a) = f(a + c) \qquad (a, c \in A).$$

Let G be the group generated by all the modulations, all the translations and by multiplications by complex numbers of absolute value 1. Explicitly

$$G = \{z M_\beta T_c;\ z \in \mathbb{C},\ |z| = 1,\ \beta \in \hat{A},\ c \in A\}.$$

For a set S, let $|S|$ denote the cardinality of S.

Theorem 1.1. *For any non-zero function $f : A \to \mathbb{C}$,*

(a) $$|supp\, f| \cdot |supp\, \hat{f}| \geq |A|.$$

The set of minimizers for the inequality (a), i.e. the set of functions for which the equality occurs in (a), coincides with the set of orbits

(b) $$G \cdot f$$

where $f = const\,\mathbb{I}_B$ is a constant multiple of the indicator function $\mathbb{I}_B$ of a subgroup $B \subseteq A$.

The main goal of this article is to present an elementary proof of Theorem 1.1. This shall be done in section 2. Here we shall provide a proof based on a characterization of the minimizers for the corresponding entropy inequality, [Ö-P, Theorem 1.5].

Let μ denote the counting measure on A, so that

$$\int_A f(a)\, d\mu(a) = \sum_{a \in A} f(a).$$

Then the measure μ is invariant under the translations T_c, $c \in A$. Thus μ is a Haar measure on A. Let $\hat{\mu}$ be the dual Haar measure on $\hat{A}$, so that the inverse Fourier transform is given by

$$f(a) = \int_{\hat{A}} \hat{f}(\alpha)\, d\hat{\mu}(\alpha), \qquad (\alpha \in \hat{A}).$$

Then, as is well known, $\hat{\mu}$ coincides with the counting measure on $\hat{A}$ multiplied by $\frac{1}{|A|}$.

We shall view the function $f : A \to \mathbb{C}$ as a member of the Hilbert space $L^2(A, \mu)$. Suppose $\| f \|_2 = 1$. Then, by the Plancherel formula, $\| \hat{f} \|_2 = 1$. Hence we have the entropies

$$H(|f|^2) = -\int_A |f(a)|^2 log(|f(a)|^2)\, d\mu(a),$$

$$H(|\hat{f}|^2) = -\int_{\hat{A}} |\hat{f}(\alpha)|^2 log(|\hat{f}(\alpha)|^2)\, d\hat{\mu}(\alpha),$$

where the *log* stands for the natural logarithm. Notice that $\| \mu(supp\,f)^{-1/2}\mathbb{I}_{supp\,f} \|_2 = 1$. Since the entropy of a uniform probability distribution is maximal, we have

$$H(|f|^2) \leq H(|\mu(supp\,f)^{-1/2}\mathbb{I}_{supp\,f}|^2) = log(\mu(supp\,f)).$$

Similarly

$$H(|\hat{f}|^2) \leq H(|\hat{\mu}(supp\,\hat{f})^{-1/2}\mathbb{I}_{supp\,\hat{f}}|^2) = log(\hat{\mu}(supp\,\hat{f})).$$

Hence, by the entropy inequality, [Ö-P, Theorem 1.5 (a)] or [D-C-T],

$$(1.2) \qquad log(\mu(supp\,f) \cdot \hat{\mu}(supp\,\hat{f})) \geq H(|f|^2) + H(|\hat{f}|^2) \geq 0.$$

4

This verifies the inequality (a) of Theorem 1.1.

The equality in part (a) of Theorem 1.1, together with (1.2), imply the following equality

$$H(|f|^2) + H(|\hat{f}|^2) = 0.$$
(1.3)

Hence, Theorem 1.5 (b) in [Ö-P] shows that the function f is of the desired form.

2. An elementary proof of Theorem 1.1.

For a subset $S \subseteq A$ let $S^\perp = \{\alpha \in \hat{A}, \ \alpha|_S = 1\}$. Then, as is well known, for any subgroup $B \subseteq A$,

$$|B| \cdot |B^\perp| = |A|.$$
(2.1)

Consider a non-zero function $f : A \to \mathbb{C}$, as in Theorem 1.1. We may, and shall, assume that $0 \in supp\, f$ and that $0 \in supp\, \hat{f}$ (translating and modulating f if necessary). Notice first that, in order to prove the theorem, it will suffice to show that $supp\, f$ is a subgroup of A. Indeed, since the Fourier transform $\hat{f}$ is invariant under the translations by $(-supp\, f)^\perp$, $(\hat{f}(\alpha\beta) = \hat{f}(\alpha)$ for all $\alpha \in \hat{A}$ and all $\beta \in (-supp\, f)^\perp)$, the equation (2.1) implies the inequality (a) of the theorem. Furthermore, the equality in part (a) of Theorem 1.1, implies that $\hat{f}$ is supported on $B^\perp$, where $B = supp\, f$. Since $\hat{f}$ is $B^\perp$-invariant, $\hat{f}$ is a constant on $B^\perp$. Then f is a constant multiple of $\mathbb{I}_B$. Thus we shall be done as soon as we verify the following Proposition.

Proposition 2.2. *For a finite abelian group A and a function $f : A \to \mathbb{C}$ we have*
(a) if $f \neq 0$, then $|supp\, f| \cdot |supp\, \hat{f}| \geq |A|$;
(b) if $|supp\, f| \cdot |supp\, \hat{f}| = |A|$ and $0 \in supp\, f$, then $supp\, f$ is a subgroup of A.

Proof. When the group A is cyclic the Proposition follows from [D-S]. Thus we may assume that there are nontrivial subgroups $B, C \subseteq A$ such that

$$A = B \oplus C.$$

Then

$$\hat{A} = \hat{B} \oplus \hat{C}.$$

For a function $f : A \to \mathbb{C}$ let

$$f_c(b) = f(b+c) \qquad (b \in B, \ c \in C),$$

and let

$$g_\beta(c) = \hat{f}_c(\beta) \qquad (\beta \in \hat{B}, \ c \in C).$$

Then, in particular,

$$(2.3) \qquad \hat{f}(\beta + \gamma) = \hat{g}_\beta(\gamma) \qquad (\beta \in \hat{B}, \ \gamma \in \hat{C}).$$

We proceed via the induction on $|A|$. Suppose the proposition holds for the groups B and C. Let

$$\mathcal{B} = \{\beta \in \hat{B}; \ g_\beta \neq 0\}, \ \text{and} \ \mathcal{C} = \{c \in C; \ f_c \neq 0\}.$$

Pick $c \in \mathcal{C}$ with $|supp\, f_c|$ minimal. Then

$$(2.4) \qquad |supp\, f_c| \leq |supp\, f|/|\mathcal{C}|.$$

Hence, by the inductive assumption,

$$(2.5) \qquad |supp\, \hat{f}_c| \geq |B|/|supp\, f_c|.$$

From (2.4) and (2.5) we deduce

$$(2.6) \qquad |supp\, \hat{f}_c| \geq |B| \cdot |\mathcal{C}|/|supp\, f|.$$

Notice that $supp\, \hat{f}_c \subseteq \mathcal{B}$, so that

$$(2.7) \qquad |supp\, \hat{f}_c| \leq |\mathcal{B}|.$$

Also,

$$(2.8) \qquad supp\, g_\beta \subseteq \mathcal{C} \qquad (\beta \in \mathcal{B}).$$

By the inductive assumption and by (2.8) we have

$$(2.9) \qquad |supp\, \hat{g}_\beta| \geq |C|/|supp\, g_\beta| \geq |C|/|\mathcal{C}|.$$

We see from (2.3) that

$$supp\, \hat{f} = \bigcup_{\beta \in \mathcal{B}} supp\, \hat{g}_\beta,$$

where the union is disjoint. Therefore,

$$(2.10) \qquad |supp\, \hat{f}| = \sum_{\beta \in \mathcal{B}} |supp\, \hat{g}_\beta| \geq \sum_{\beta \in \mathcal{B}} |C|/|\mathcal{C}| = |C| \cdot |\mathcal{B}|/|\mathcal{C}|,$$

where the inequality follows from (2.9). We see from (2.6) and (2.7) that

$$(2.11) \qquad |supp\, f| \geq |B| \cdot |\mathcal{C}|/|supp\, \hat{f}_c| \geq |B| \cdot |\mathcal{C}|/|\mathcal{B}|.$$

By combining (2.10) and (2.11) we get

$$(2.12) \qquad |supp\, f| \cdot |supp\, \hat{f}| \geq |B| \cdot |C| = |A|.$$

This verifies the inequality (a) in our Proposition 2.2.

Suppose from now on that we have equality in (2.12). Also, we may and shall assume that $0 \in supp\, \hat{f}$.

The equality in (2.12) forces equalities in (2.4), (2.5), (2.6), (2.7), (2.9) and (2.10). Therefore

$$(2.13) \qquad |supp\, f_c| = |supp\, f|/|\mathcal{C}| \qquad (c \in \mathcal{C}),$$

$$(2.14) \qquad |supp\, f_c| \cdot |supp\, \hat{f}_c| = |B| \qquad (c \in \mathcal{C}),$$

$$(2.15) \qquad supp\, \hat{f}_c = \mathcal{B} \qquad (c \in \mathcal{C}),$$

$$(2.16) \qquad supp\, g_\beta = \mathcal{C} \qquad (\beta \in \mathcal{B}),$$

$$(2.17) \qquad |supp\, g_\beta| \cdot |supp\, \hat{g}_\beta| = |C| \qquad (\beta \in \mathcal{B}).$$

Also,

$$(2.18) \qquad 0 \in \mathcal{B}, \text{ and } 0 \in \mathcal{C},$$

because

(2.19) $$\hat{g}_0(0) = \hat{f}(0) \neq 0, \text{ and } f_0(0) = f(0) \neq 0.$$

By the inductive assumption, (2.14) and by (2.19), $supp\, f_0$ is a subgroup of B. We see from (2.14) and (2.19) that $supp\, \hat{f}_0 = (supp\, f_0)^{\perp}$ is a subgroup of $\hat{B}$. Hence, (2.15) implies that $\mathcal{B}$ is a subgroup of $\hat{B}$ and $\hat{f}_0 = const\, \mathbb{I}_{\mathcal{B}}$. Similarly

(2.20) $$\mathcal{C} = supp\, g_0 \text{ is a subgroup of } C \text{ and } g_0 = const\, \mathbb{I}_{\mathcal{C}}.$$

By the inductive assumption and by (2.14), $supp\, f_c$ is a translation of the subgroup $(supp\, \hat{f}_c)^{\perp} = \mathcal{B}^{\perp} \subseteq B$. Thus there is a function $\phi : C \to B$ such that

(2.21) $$supp\, f_c = \mathcal{B}^{\perp} + \phi(c) \qquad (c \in \mathcal{C}),$$

where $\phi(0) = 0$. Again, by (2.14) and (2.21),

(2.22) $$\hat{f}_c(\beta) = \beta(\phi(c))\, \hat{f}_c(0) \qquad (\beta \in \mathcal{B},\ c \in \mathcal{C}).$$

Notice that $\hat{f}_c(0) = g_0(c) = g_0(0)$. Thus (2.22) may be rewritten as

(2.23) $$\hat{f}_c(\beta) = \beta(\phi(c))\, g_0(0), \qquad (\beta \in \mathcal{B},\ c \in \mathcal{C}).$$

Similarly, for some $\gamma_\beta \in \hat{C}$,

(2.24) $$g_\beta(c) = \gamma_\beta(c)\, g_\beta(0) \qquad (c \in \mathcal{C}).$$

Since $g_\beta(c) = \hat{f}_c(\beta)$, we have

$$g_\beta(0) = \hat{f}_0(\beta) = \hat{f}_0(0) = g_0(0).$$

Thus (2.24) may be rewritten as

(2.25) $$\hat{f}_c(\beta) = \gamma_\beta(c)\, g_0(0) \qquad (\beta \in \mathcal{B},\ c \in \mathcal{C},).$$

By combining (2.23) and (2.25) we deduce the following equality,

$$\beta(\phi(c)) = \gamma_\beta(c) \qquad (\beta \in \mathcal{B},\ c \in \mathcal{C}).$$

Hence for $\beta \in \mathcal{B}$, and for $c_1, c_2 \in \mathcal{C}$,
$$\beta(\phi(c_1) + \phi(c_2) - \phi(c_1 + c_2))$$
$$= \beta(\phi(c_1))\beta(\phi(c_2))\beta(\phi(c_1 + c_2))^{-1}$$
$$= \gamma_\beta(c_1)\gamma_\beta(c_2)\gamma_\beta(c_1 + c_2)^{-1} = \gamma_\beta(0) = 1.$$

Therefore

(2.26) $$\phi(c_1) + \phi(c_2) - \phi(c_1 + c_2) \in \mathcal{B}^{\perp} \qquad (c_1, c_2 \in \mathcal{C}).$$

We see from (2.21) and (2.26) that

$$supp\, f = \bigcup_{c \in \mathcal{C}} supp\, f_c = \bigcup_{c \in \mathcal{C}} (\mathcal{B}^{\perp} + \phi(c))$$

is closed under addition. Therefore $supp\, f$ is a subgroup of A. $\square$
